The Life of a Router

- Do
 - Find Path
 - Forward, forward, forward, forward, forward
 - Find Path
 - Forward, forward, forward, forward, forward
- Repeat until powered off
- Two basic operations –
 - Construct the routing table – **the control plane**
 - Do a routing match and forward the packet to a dedicated interface – **the data plane**

Evolution of Router Architecture

- 1st Generation (Until 1980's): Standard Computer
- 2nd Generation (Early 1990's): Delegate to interfaces
- 3rd Generation (Late 1990's): Distributed Architecture
- 4th Generation (Early 2000's): Distributed over multiple racks
- 5th Generation (Today): Software Defined Routing

Basic Architectural Components of a Router

Router Hardware

- Processor is responsible for control functions (**route processors**)
 - Construct the routing table based on the routing algorithm
- Forwarding is done at the interface card
 - Route match needs to be very fast
 - Specialized hardware – Ternary Content-Addressable Memory (TCAM)

Slotted Chassis – The Physical Infrastructure for Routers

- Large routers are built as slotted chassis
 - Interface cards are inserted in the slots
 - Route processor is also inserted at a slot
- Simplifies repairs and upgrades of components

Functional Components

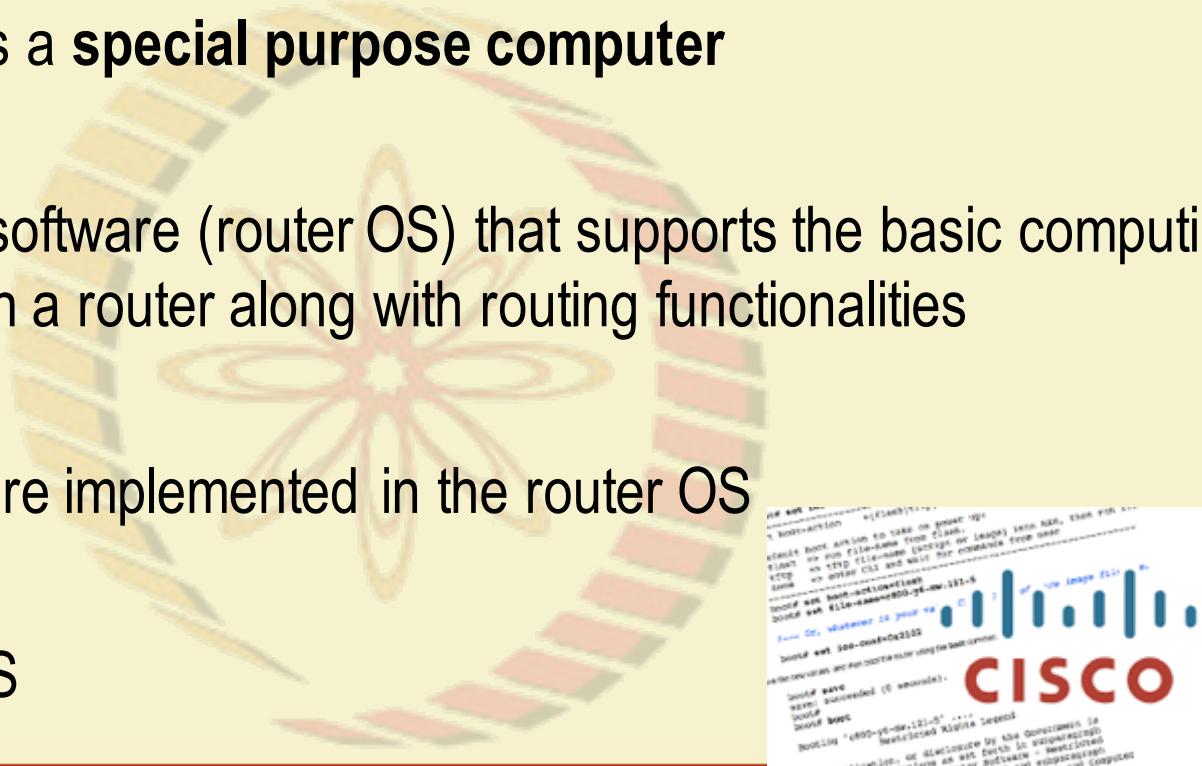

IIT KHARAGPUR

NPTEL
ONLINE
CERTIFICATION COURSES

Control Plane in a Router

- Note that a router is a **special purpose computer**
 - Implemented as a software (router OS) that supports the basic computing functionalities to run a router along with routing functionalities
 - Routing protocols are implemented in the router OS
 - Example: Cisco IOS

NPTEL ONLINE
CERTIFICATION COURSES

Routing Functions

- **Route Calculation**
- **Maintenance of the routing table**
- **Execution of the routing protocol**
- On commercial routers, routing functions are handled by a single general purpose processor, called the **route processor**

IIT KHARAGPUR

NPTEL
NPTEL ONLINE
CERTIFICATION COURSES

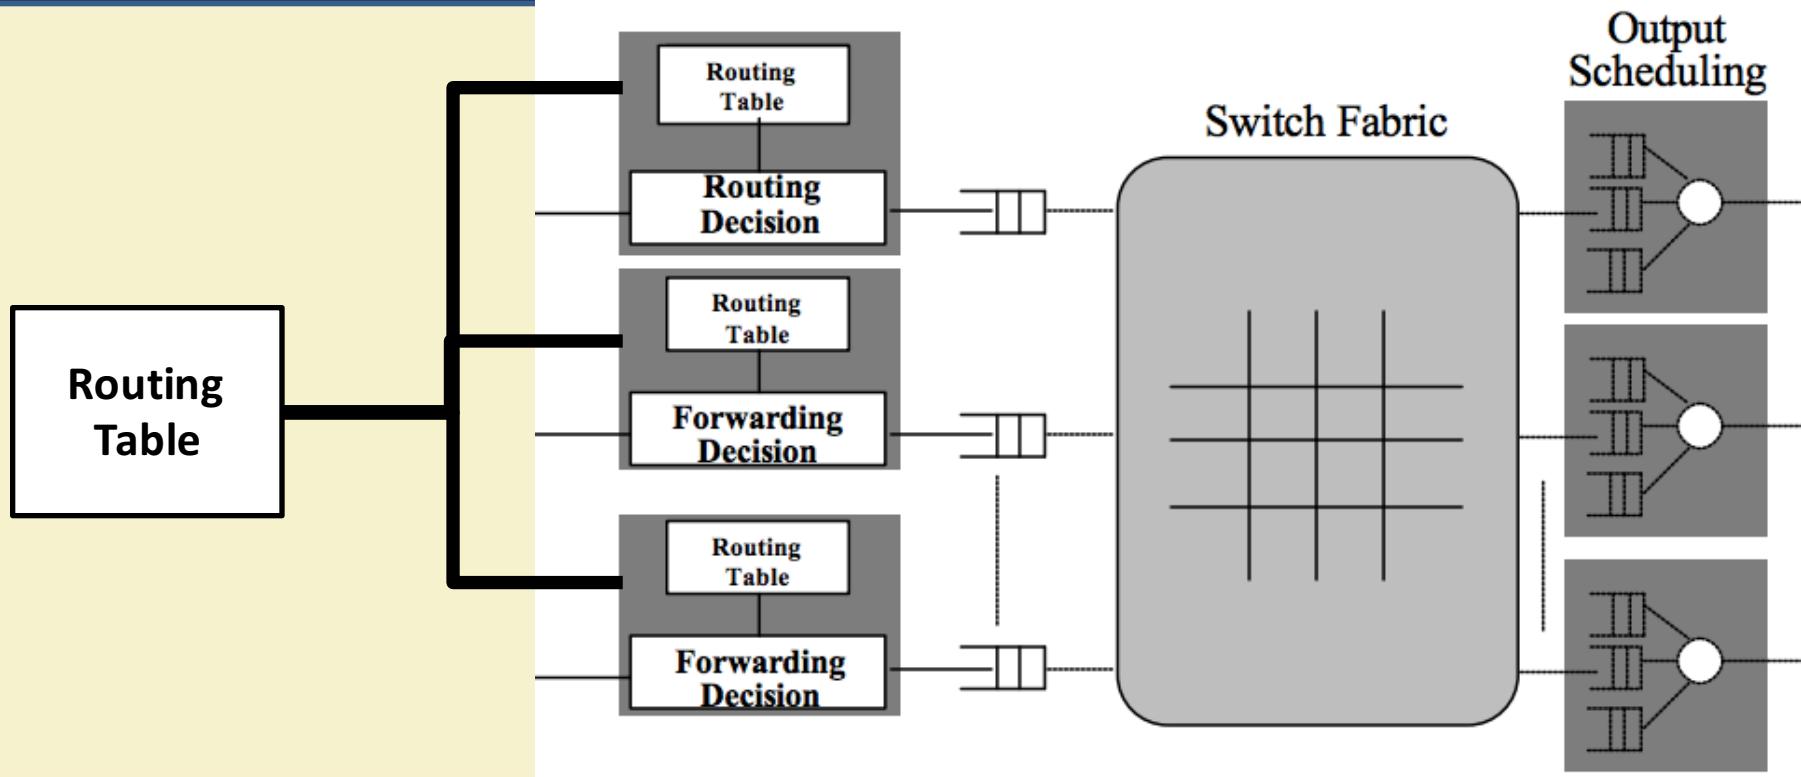

Data Plane of a Router

- Implement forwarding functionalities – make a route lookup and forward the packet at the destination interface
- Functionality is similar to a L2 switch – use switch fabric (the mapping from input ports to output ports) to forward the packet from one interface to another
- Maintains interface buffer – to implement store and forward functionality

IP Forwarding

- Per packet processing of the IP packets
- IP forwarding is distributed, handled by individual interface controllers
- Special hardware devices are used - TCAM

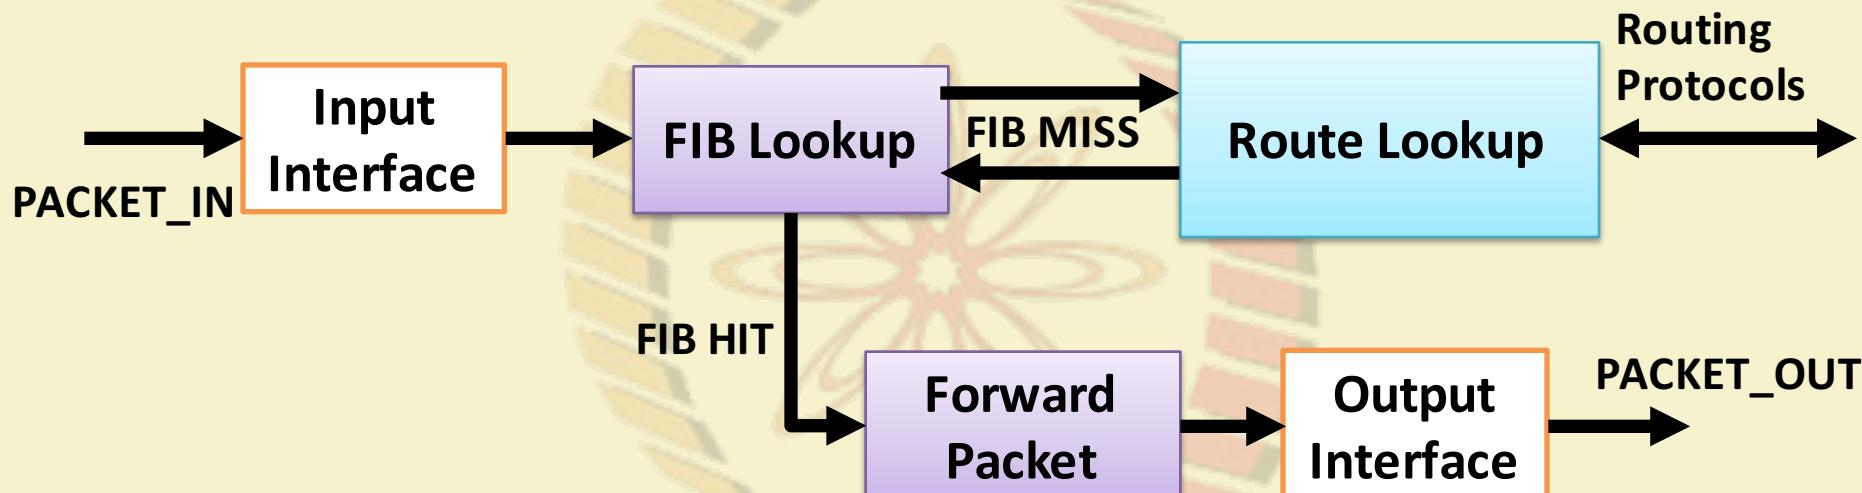

Per Packet Processing – Basic Architectural Components

Forwarding Information Base (FIB)

- The interfaces maintains a *forwarding information base* (FIB) – a mapping from input interface to output interface
- A replica of the routing table used at the interfaces for making the forwarding decision

Forwarding Information Base (FIB)

IIT KHARAGPUR

NPTEL
ONLINE
CERTIFICATION COURSES

Difference between RIB and FIB

- **Routing Information Base (RIB)** – The routing table, implemented in software, is maintained at the control plane
- **Forwarding Information Base (FIB)** – The copy of the required routes maintained in interface TCAM hardware
- RIB is dynamic and maintains entire routing information, FIB is updated whenever required

RIB and FIB

The RIB

IP Routers - Internals and Demo

Basic Architectural Components of a Router

Functional Components

Ternary Content Addressable Memory (TCAM)

- Specialized high speed memory - searches its entire content in a single clock cycle
- **Ternary** - store and query data using three different inputs - 0, 1 and X (don't care or wildcard)
- Searching is based on pattern matching, ex. 110X - match content that starts with 110*

IIT KHARAGPUR

NPTEL
NPTEL ONLINE
CERTIFICATION COURSES

CAM vs RAM

- RAM is accessed via the address where the data is stored
- CAM can be addressed by performing a query for the content itself - retrieves the address where data is found
 - Opposite to RAM !!
- Much faster than RAM

Software Defined Networking

Software-defined networking (SDN) is a network framework which involves separating a network's **control functions** from its **data forwarding functions**, centralizing its intelligence, and abstracting its underlying architecture from applications and services.

Control and Data Plane

- **Control plane**
 - The module which takes all decisions, basically an instructor
 - The routing algorithm

- **Data plane**
 - The module which carries out the tasks given by the control plane
 - Forwarding of Packets

Control and Data Plane

- Traditional networking devices are proprietary
 - Vendors decide software (control plane) and hardware (data plane)
- No standardization

*These two modules are “baked” in
Unchangeable*

What does separating control and data plane mean?

But what if they were separate?

- Vendors only provide the hardware (data plane)
- We decide the control plane by writing custom logic – **the software**

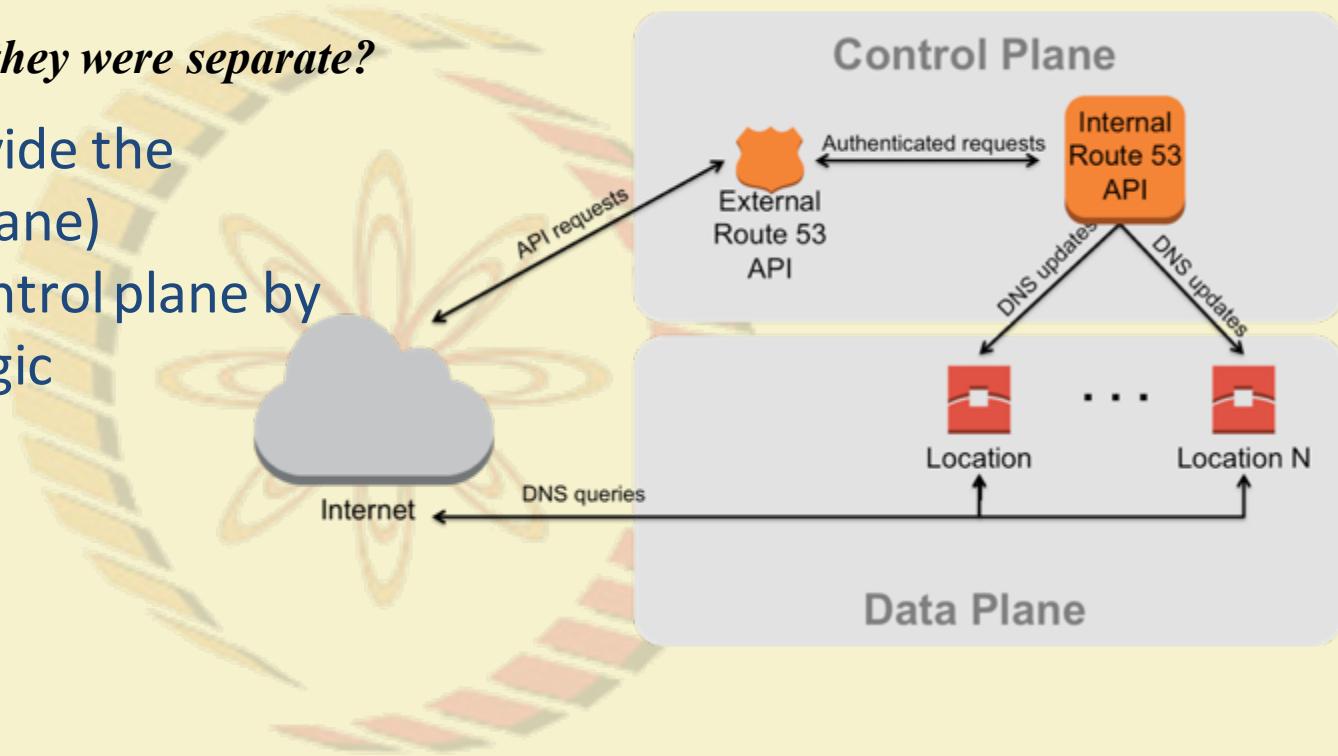

NPTEL ONLINE
CERTIFICATION COURSES

What does separating control and data plane mean?

But what if they were separate?

- Vendors only provide the hardware (data plane)
- We decide the control plane by writing custom logic

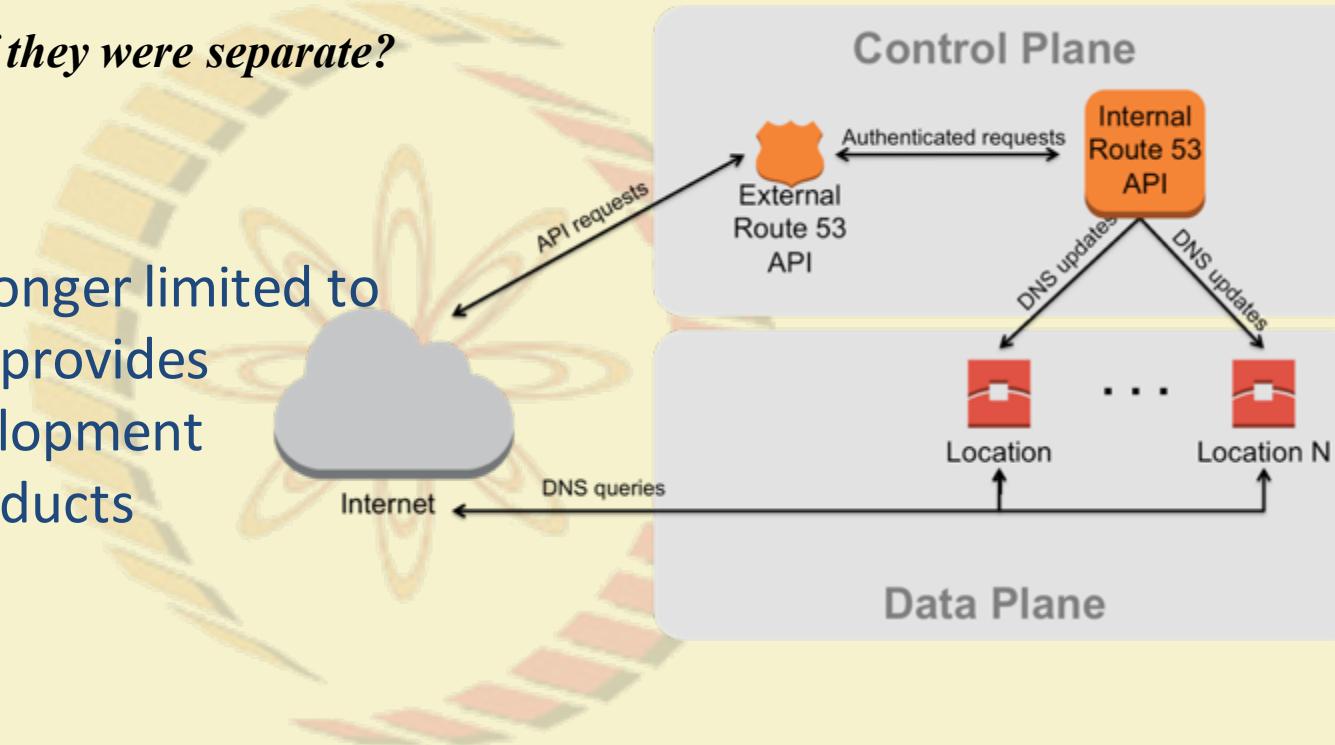

What does separating control and data plane mean?

But what if they were separate?

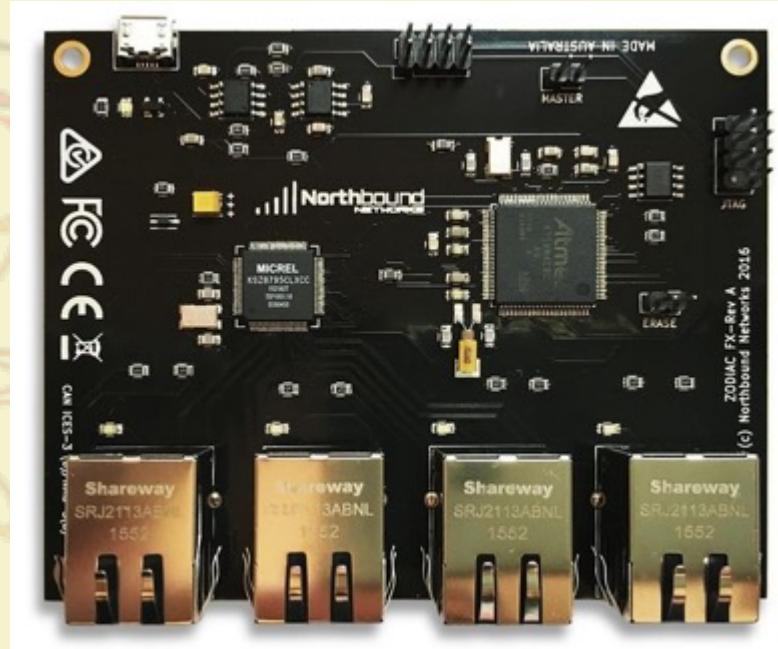

Advantages:

- Features are no longer limited to what the vendor provides
- Community development
- Longer life of products

How Does SDN Work

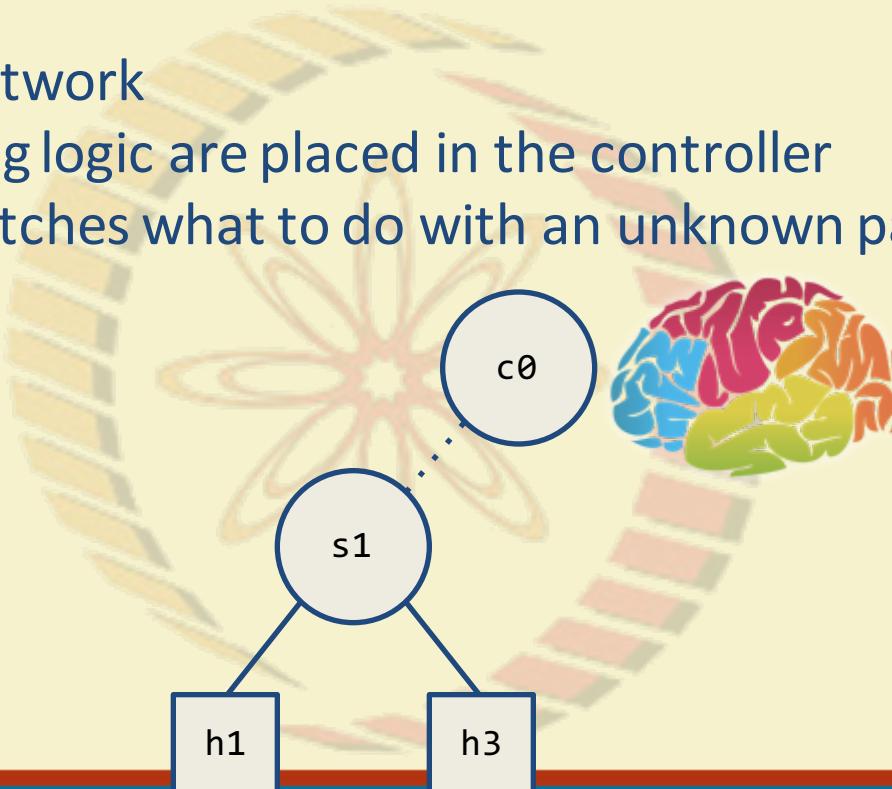

- Compared to traditional networks, a software defined network has 2 types of devices
 - Controller
 - Switches
- The switches in SDN are **blind**
 - No built-in features
 - Need to be instructed by the controller

Zodiac FX - A Tiny SDN Switch

SDN Controller

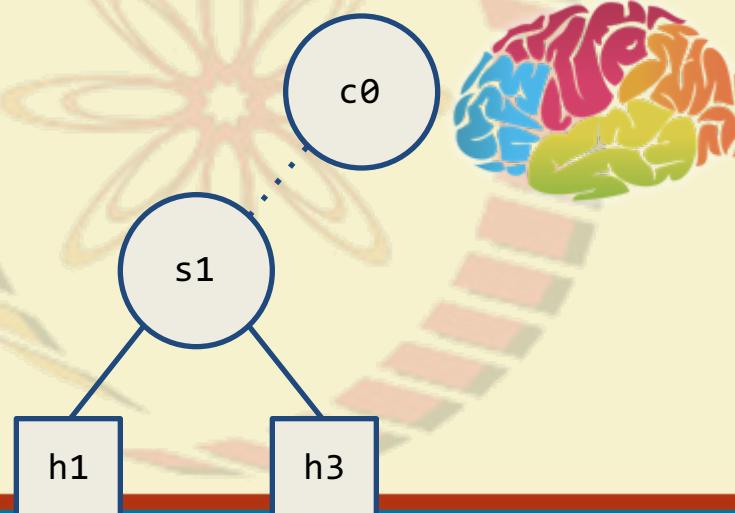

- “**Brains**” of the network
- All policies, routing logic are placed in the controller
- “**Teaches**” the switches what to do with an unknown packet

SDN Controller

- “Brains” of the network
- All policies, routing logic are placed in the controller
- “Teaches” the switches what to do with an unknown packet

Let us now see a scenario where a packet wants to go from $h1$ to $h3$ in an SDN environment

Forwarding Request from h1 to s1

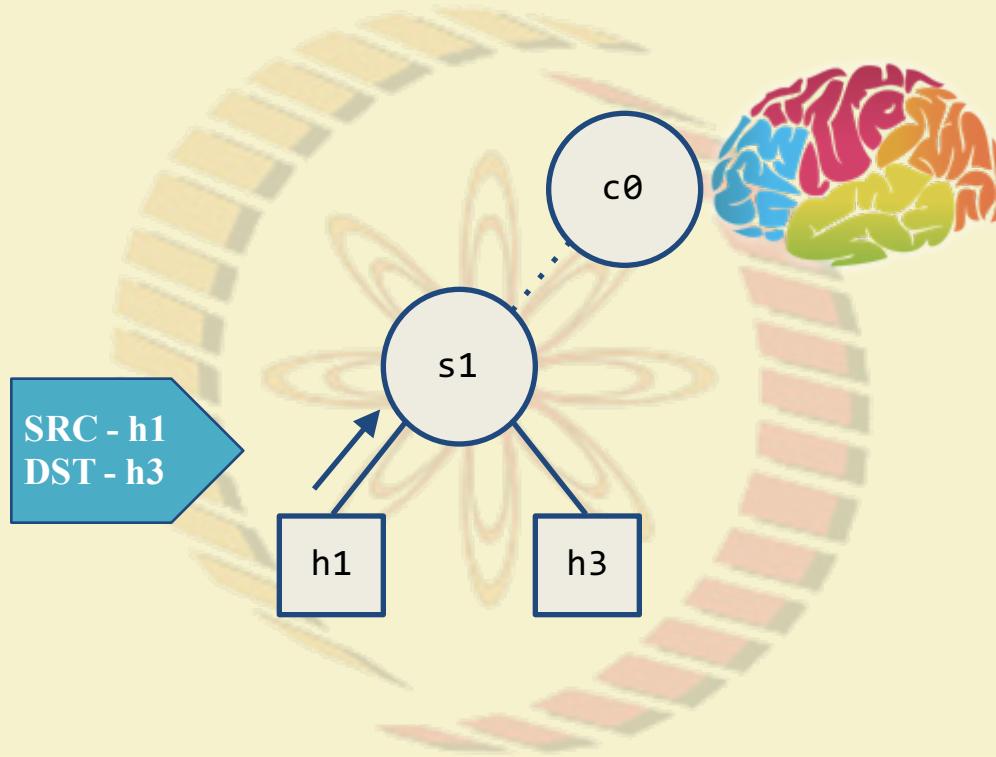

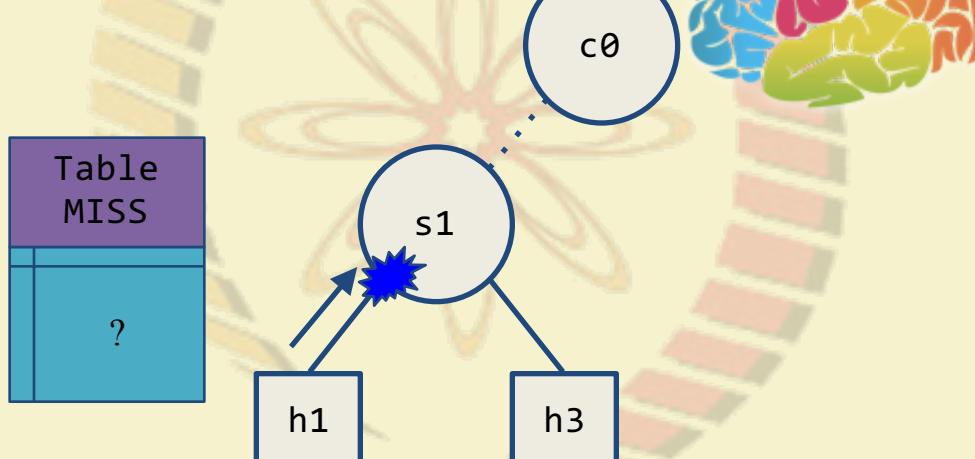

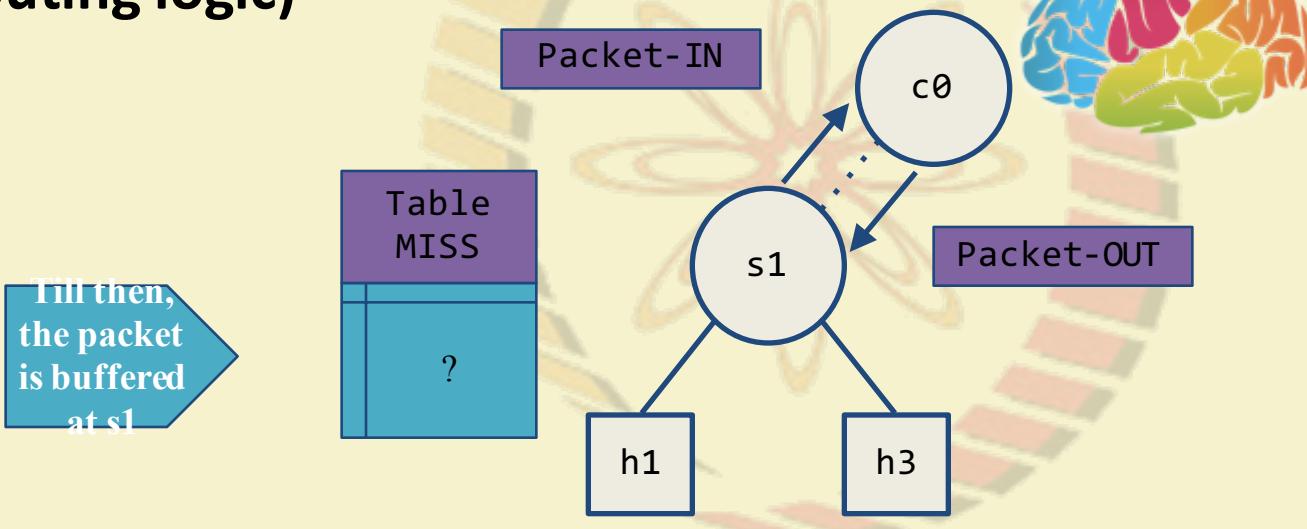

Table Miss at s1

No rule is there for $h1 \rightarrow h2$ at the beginning, so a FIB miss at S1

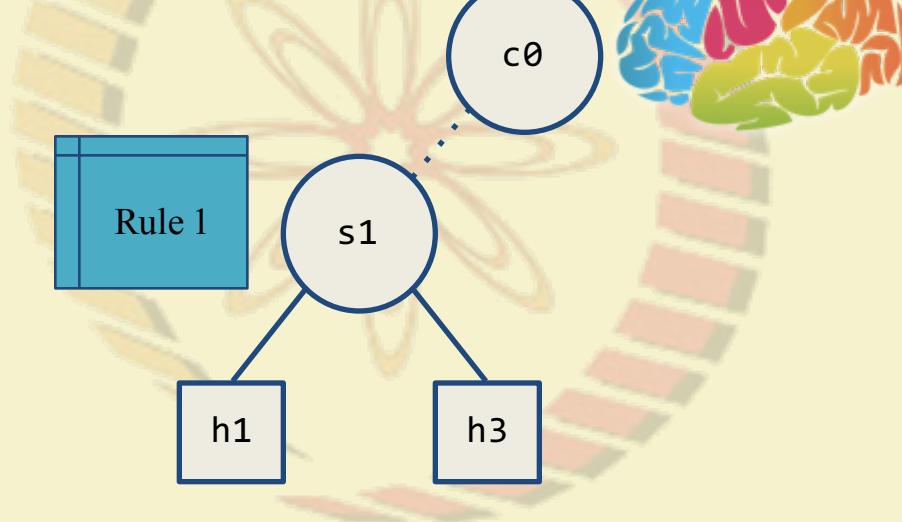

Packet-IN to Controller

The controller generates the rule based on a software program (the routing logic)

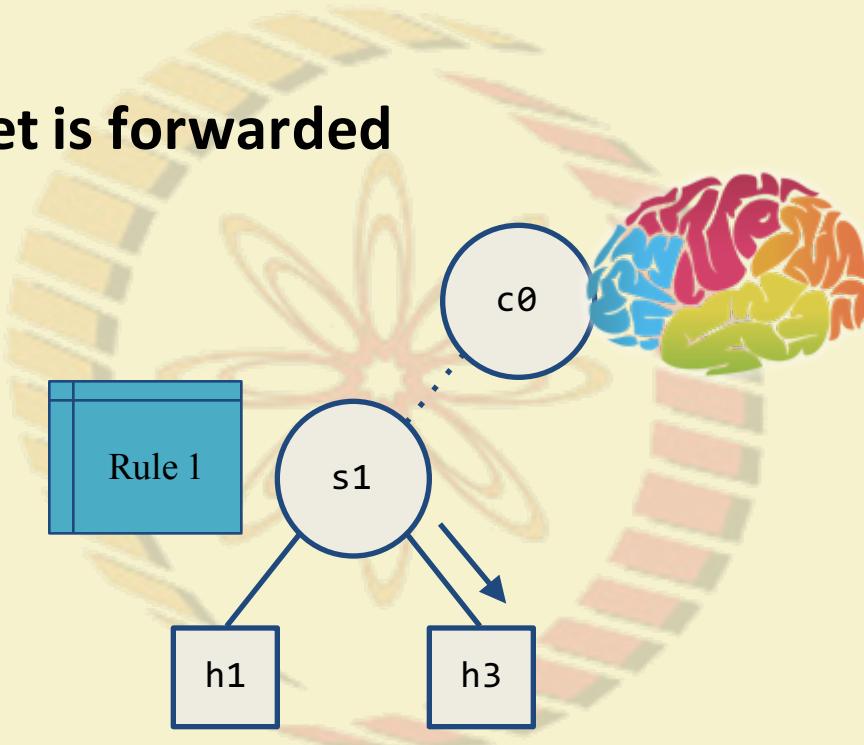

Flow Rule Set at S1...

The rule is installed at the FIB of S1

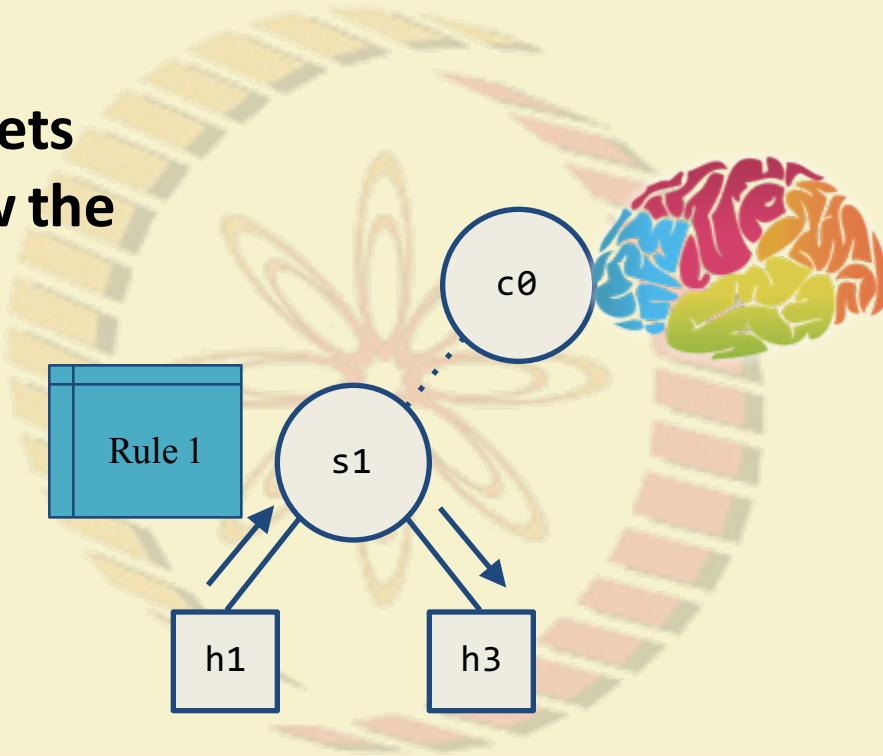

All Future Packets from h1->h3

The buffered packet is forwarded based on that rule

Buffered Packet Forwarded to h3...

All the future packets
from h1->h2 follow the
same rule

The SDN Architecture

OpenFlow Messages

- Once TCP connection is made, *OpenFlow HELLO* message is exchanged between the controller and the switch
 - Negotiate OpenFlow version
 - Agree on highest version supported.
- Controller sends *OpenFlow Feature Request* message
 - Get the datapath ID of the switch
 - Determine what features switch supports
- Based on the application program, OpenFlow messages for switch configurations (flow entries) are sent

OpenFlow Messages

- To check connection aliveness, *echo request* and *echo reply* OpenFlow messages are sent from either controller or switch.
- To group flow entries, groups are configured by the controller through group messages that can be stored into group tables inside switches
- To get statistics details from the switch, OpenFlow messages like *flow stats*, *port stats*, *queue stats*, *group stats*, *table stats*, etc. can be sent from controller.
- Asynchronous OpenFlow messages like *flow rule removal from a switch*, *configuration apply fail error from switch*, *port up/down status from switch*, etc. can be sent from switch to update controller.
